

# worth protecting

Open fields of natural grasslands are home to special plants and secretive animals, and support productive cattle businesses by providing palatable feed.

Natural grasslands are an essential part of our local landscape and they need your help to survive.

#### **IMPORTANT HABITAT**

More than 340 species of plants and animals live in the grasslands of central Queensland. A number of these species are found only in grassland vegetation. Like rainforests, natural grasslands are complex in their structure. The large variety of grasses and forbs, along with varying inter-tussock spaces and soil cracks, provide different habitat niches for animals.

The narrow-nosed planigale (*Planigale tenuirostris*), a small carnivorous marsupial, forages and shelters in the deep cracking soils while several species of quail thrive in the thick ground level vegetation.

Sadly many species are unable to survive modification of their habitat or the introduction of weeds and exotic pasture species. The vulnerable king bluegrass (*Dichanthium queenslandicum*) is one species that is sensitive to habitat change, being unable to survive continued heavy grazing.

#### PRODUCTIVE PLACES

Natural grasslands are made up of perennial grasses, annual grasses and forbs; this diversity provides good quality fodder for grazing stock throughout the year. Native grasses and forbs are often sought after by stock for their high nutritional value and palatability. Research has shown the crude protein levels can be up to 10 percent with 62 percent digestibility.

#### IN NEED OF PROTECTION

Natural grasslands of the Central Highlands and the Northern Fitzroy Basin once covered an area of approximately 1.2 million hectares, extending from Collinsville in the north to Carnarvon National Park in the south. Now, less than half remains.

Threats to native grasslands include high grazing pressure, cropping and pasture improvement, weeds, mining activities and the construction of roads and other infrastructure.

Because of the severe decline and continuing threats to this ecological community these natural grasslands are now protected under the *Environment Protection and Biodiversity Conservation Act 1999*. The Fitzroy Basin Association Incorporated (FBA) is working to help conserve this significant grassland community through funding from the Australian Government's Caring for our Country.

## TIPS FOR MANAGING NATURAL GRASSLANDS

Grazing management: Spelling or light stocking over the summer growing period will encourage seed set and seedling establishment, and promote healthy perennial grass tussock and root growth.

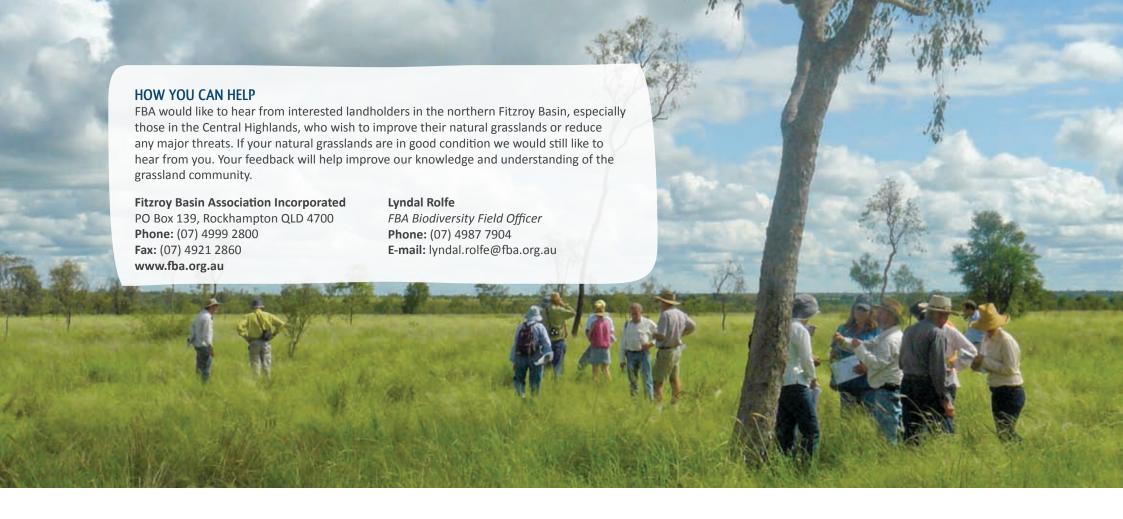

Burning: Using fire to reduce fuel loads and rejuvenate pasture every 4–5 years will not degrade the grassland. Cool burns, in late spring after rainfall, prior to the wet season (November–February) are best. Low intensity patchy mosaic burns are recommended.

Weed control: Heavy infestations of parthenium and other weeds is an indicator that grasslands are in poor condition. Extended periods of spelling may be required to fully recover grasslands from parthenium and other weed infestations. Aerial and large scale weed control spraying can result in the loss of grassland species. There are many successful biological control agents available for parthenium control.

Cultivation: Keep in mind that small patches of grassland within a cultivation area are very important refuges for native plants and animals. It is important that chemical use and other farming practices do not have an adverse effect on these areas.

Rehabilitation: The use of native seed and local topsoil ensures that the integrity of the remaining grassland is maintained and the long term success of the rehabilitation project. The use of invasive pasture species such as buffel grass (Cenchrus ciliaris) or rhodes grass species (Chloris species) should always be avoided.

### BELYANDO COBBLER'S-PEG ORANBAH The endangered Belyando Cobbler's-Peg (Trioncinia retroflexa) was thought to be extinct until it was rediscovered at several locations near Springsure and Clermont in Central Queensland. The Belyando cobbler's-peg is a short lived perennial daisy, surviving up to five years, found growing only in grasslands on basalt and cracking clay soils. It is drought and fire tolerant, however its current ROCKHAMPTON distribution suggest that it is sensitive DINGO to continuous grazing. Grassland communities within stock routes and other reserves are important habitat for the survival of this species.
